# Excess phosphorus causes eutrophication

- External inputs of P: runoff from fertilized fields or point sources
- Eutrophication → algae and microorganisms ↑: affects ecological state of water bodies
- Phosphate concentration in European rivers has halved in the last decade: thanks to protective Directives (e.g., WFD, UWWTD, MSFD, ...)
- In most EU countries more than 40% of aquatic ecosystems are at risk
- Global warming → intensified eutrophication by promoting the growth of algae

## P as critical raw material

- Phosphorite (phosphate rock): 81%, P: 100% dependent on third countries for its supply
- Their end-of-life recycling rate is very low (Phosphorite: 17%, P: 0%)
- Annual extraction of P is approximately 53 million tons  $P_2O_5$  (80% is used as fertilizer)
- Phosphorite: depleted within 50-100 years

Disadvantages

sensitive to influent flow and pollution load variations

Biological method

large sludge production, secondary contamination

Chemical method

P removal technologies

Adsorption

Cheap and simple operation, high removal efficiency  
Both removal and recovery

P recovery

adsorption materials

Phosphate adsorption on Fe-coated biochar ( *Yang et al., 2018* )

## Fe-coated Biochar

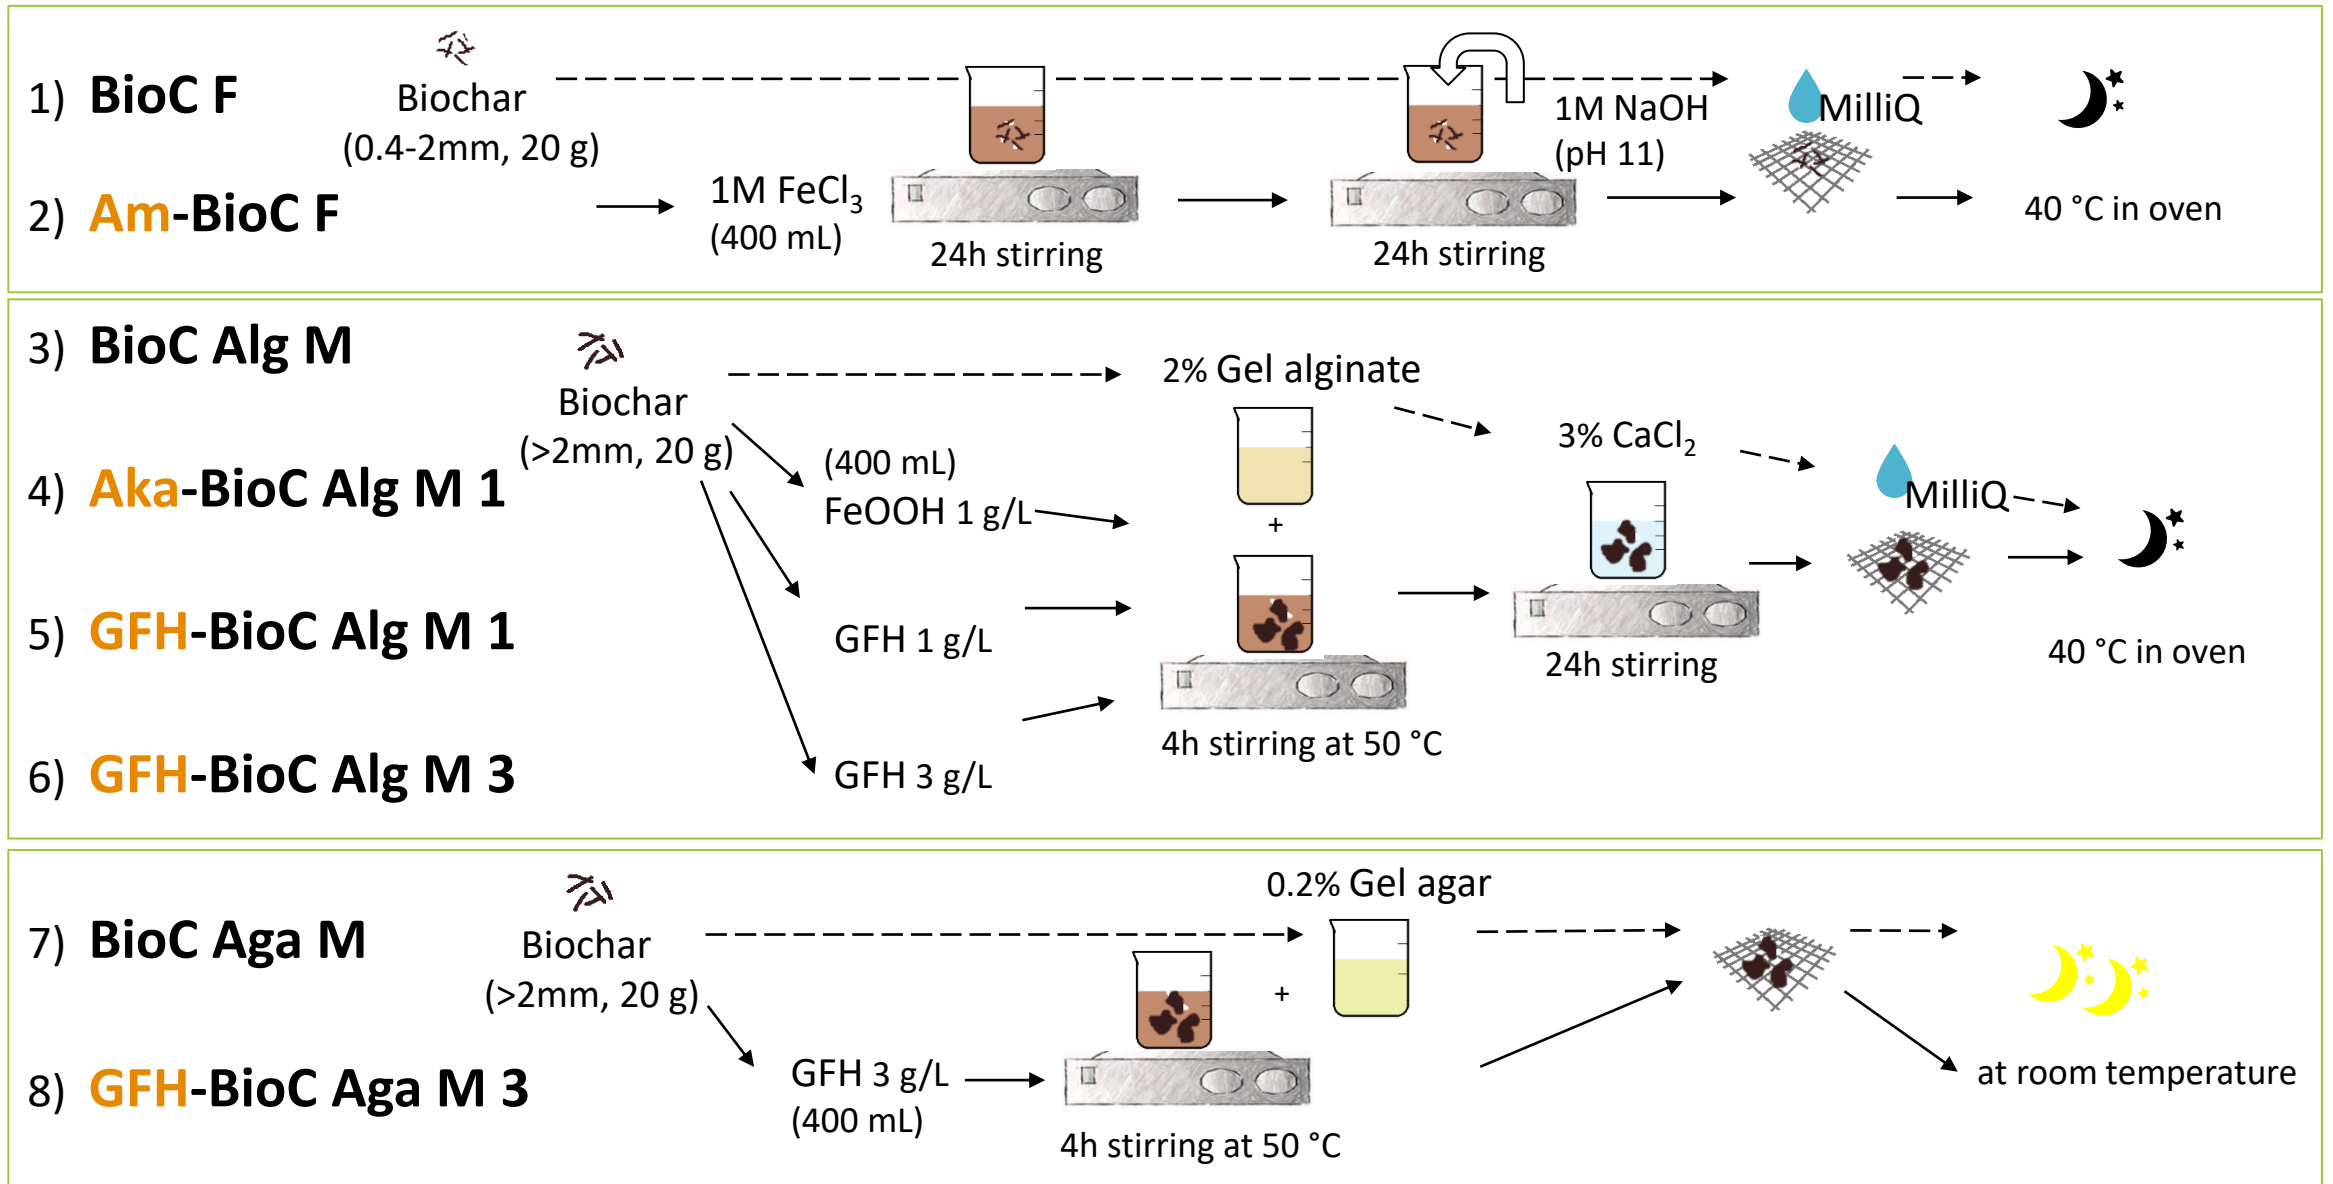

Carbon-rich material obtained by anaerobic pyrolysis of organic materials coated with FeOOH:  
high natural affinity towards phosphates  
→ enhance the phosphate adsorption capacity

## Aims of the study

- Optimization of synthesis process of different Fe-coated biochars (with different FeOOH and gels)
- Study of phosphate adsorption processes (kinetic & thermodynamic) to evaluate the removal efficiency and stability of the selected materials
- Study the microbial colonization on optimized materials in laboratory & field (wastewater)
- Evaluation of the possible reuse of the Fe-P-rich spent material as an amendment

# **MATERIALS AND METHODS**

# Preparation of 8 materials

BioC: Biochar; Materials of Iron: Am: Amorphous, Aka: Akaganeite, GFH: Granular Ferrous Hydroxide; F: fine (0.42-2mm), M: medium (>2mm); 1, 3: g FeOOH/L

# Phosphate adsorption and analytical methods

## Isotherms and adsorption kinetics

- 0.25 g of 8 materials in 100 mL of  $\text{PO}_4$  solution ( $L_1=1, L_2=5, L_3=10, L_4=20$  mg/L)
- 3 mL samples were taken ( $t_0=0, t_1=1, t_2=24$ ),  $C_0 = 5$  mg/L  $\text{PO}_4$

## Adsorption in consecutive cycles in synthetic waters and real matrices

500 mg of 8 materials in 250 mL of MilliQ or treated wastewater ( $C_0=5$  mg/L  $\text{PO}_4$ ) stirred for 24h X 3 consecutive cycles

## Concentration of $\text{PO}_4$ and total Fe

UV-VIS Spectrophotometry

# Microbial biomass development

## Submerged in the wastewater treatment plant

2 g of selected materials submerged for 14 days

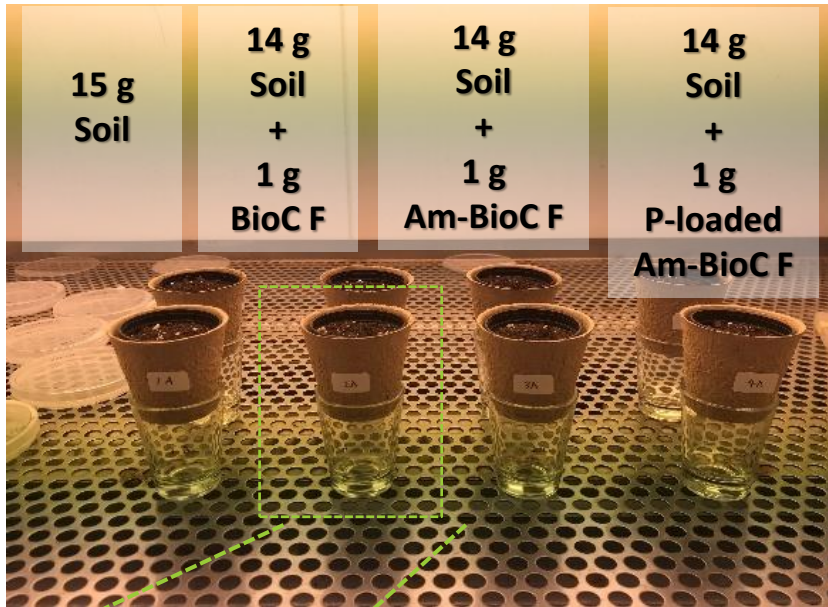

## Incubation in laboratory conditions

1.5 g of biochar (BioC F, Am-BioC F, and P-loaded Am-BioC F) :  
incubated for one month in 1 L aerated reactors filled with wastewater

**Bacterial abundance:** epifluorescence microscopy

# PO<sub>4</sub> release in soil by P-loaded biochar

To evaluate the release and retention capacity of PO<sub>4</sub> by materials in the soil (1 g + 14 g of soil, 6.7%)

Each pot was watered with 20 mL of distilled water every two days X 5 cycles

After 1 h, 5 mL of samples were taken and filtered

# Plant preparation and morpho-anatomical analyses

## Plant material and incubation conditions

Seeds of *Arabidopsis thaliana* (L.) Heynh were sown on petri plates (Murashige and Skoog) with 0.5% sucrose and 0.8% agar. Incubated under long day conditions (16/8h light/dark) at  $22 \pm 2^\circ\text{C}$  and 70% relative humidity.

*A. thaliana* (L.) seedlings: transplanted 3 weeks after sowing. 10 seedlings were used per treatment and watered with 200 mL of distilled water every 4-5 days for 8 cycles.

## Plant growth

## Morpho-anatomical analyzes:

- height of the plants
- diameter of the main stem (of 5 plants and cut at 5 cm of height)
- number of siliques, length of the silique (20 siliques per treatment)

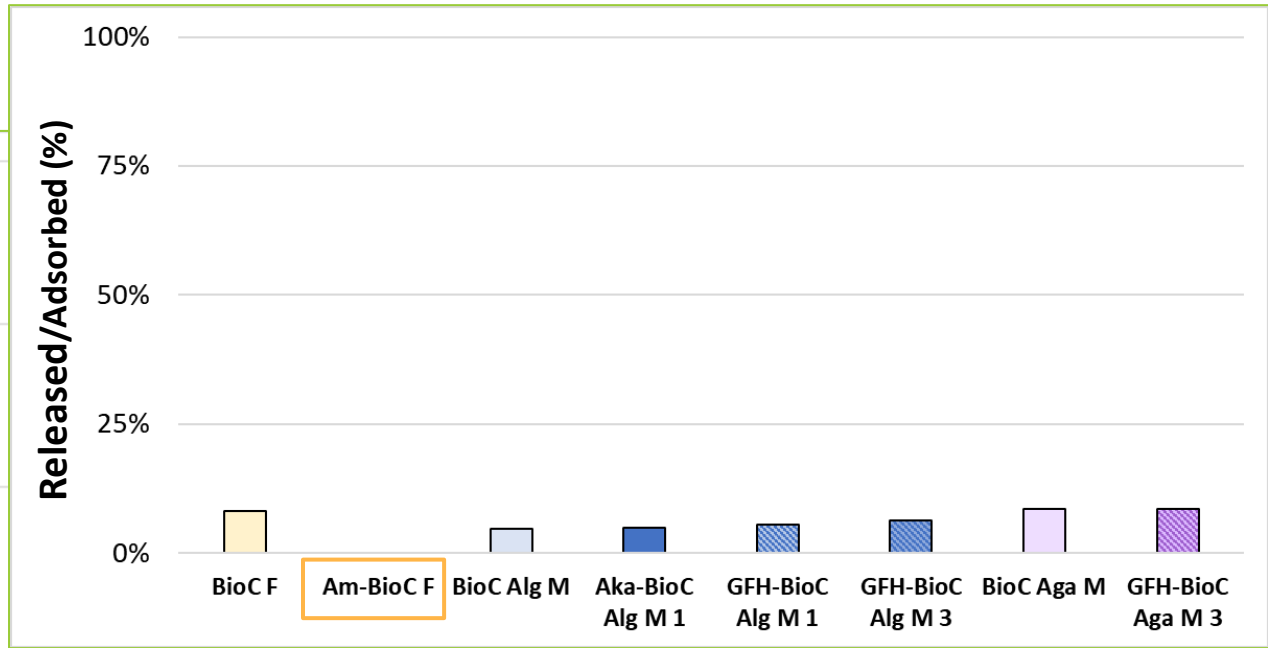

# RESULTS

## 8 optimized materials

Code	Recipe	Fe %
<b>BioC F</b>	Biochar (0.4 -2 mm)	0.0 %
<b>Am-BioC F</b>	Biochar (0.4 -2 mm) + 1M FeCl <sub>3</sub> + 1M NaOH	3.8 %
<b>BioC Alg M</b>	Biochar (>2 mm) + 2% Alginate	0.0 %
<b>Aka-BioC Alg M 1</b>	Biochar (>2 mm) + 2% Alginate + FeOOH 1 g/L	0.1 %
<b>GFH-BioC Alg M 1</b>	Biochar (>2 mm) + 2% Alginate + GFH 1 g/L	0.1 %
<b>GFH-BioC Alg M 3</b>	Biochar (>2 mm) + 2% Alginate + GFH 3 g/L	1.1 %
<b>BioC Aga M</b>	Biochar (>2 mm) + 0.2% Agar	0.0 %
<b>GFH-BioC Aga M 3</b>	Biochar (>2 mm) + 0.2% Agar + GFH 3 g/L	0.3 %

# Adsorption kinetics

Capacità di adsorbimento a 1h (max: 2 mg PO<sub>4</sub>/g abs)

BioC F	Am-BioC F	BioC Alg M	Aka-BioC Alg M 1	GFH-BioC Alg M 1	GFH-BioC Alg M 3	BioC Aga M	GFH-BioC Aga M 3
0.4	1.2	0.7	0.6	0.3	0.4	0.5	0.6

## Am-BioC F

- the best adsorption capacity of PO<sub>4</sub><sup>3-</sup> (99% removal after 24h in contact with synthetic water, C<sub>0</sub> = 5 mg/L)
- no release of PO<sub>4</sub><sup>3-</sup> adsorbed in water

# Adsorption isotherms

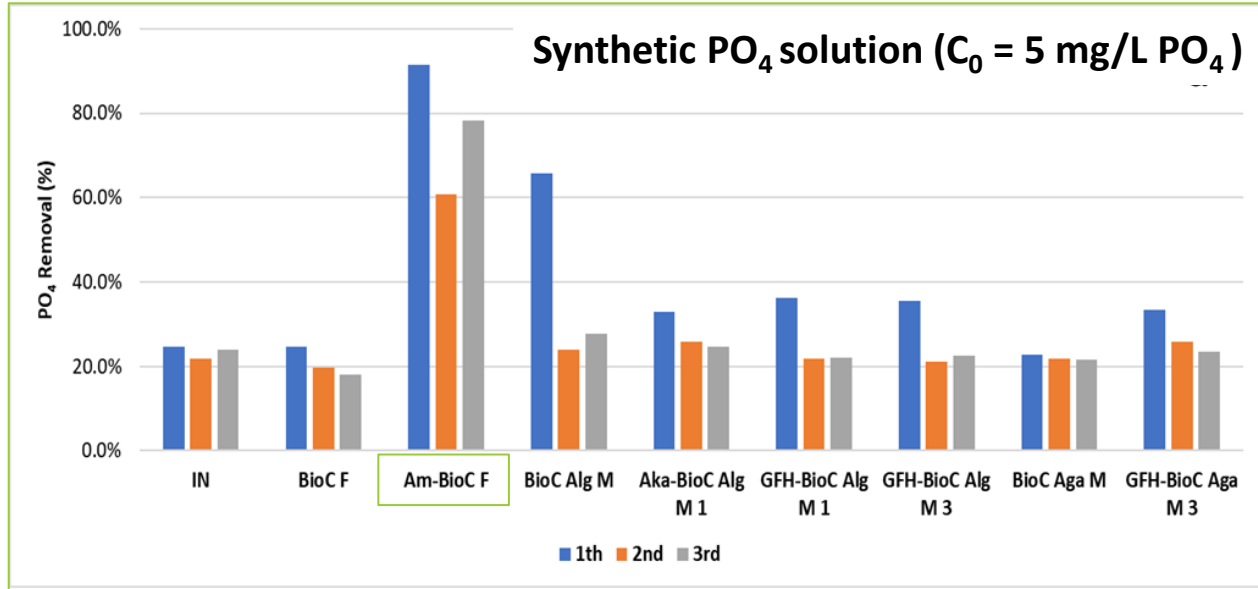

## Am-BioC F

maximum phosphate adsorption capacity ( $q_{\max}$ ) : 7.1 mg/g according to the Langmuir model

## Other materials

: 3.7-5.3 mg/g

# Adsorption at 3 cycles of batch experiment

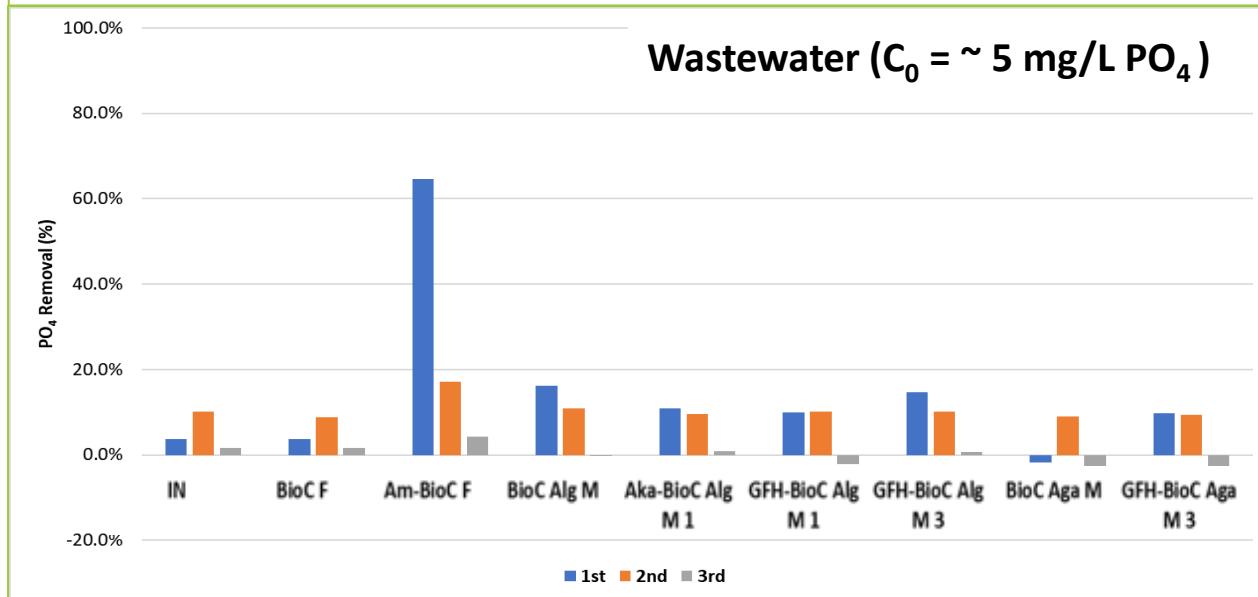

## Am-BioC F

80% removal rate after the 3rd cycle

## Other materials: 20%

$\text{PO}_4$  saturated surface area disturbed the following adsorption

The removal rate has drastically  $\searrow$  for all materials  $\rightarrow$  presence of complexing agents and biomass

Should be carefully considered in the use of modified biochar for long-term exposure

# Microbial biomass on materials

## Aka-BioC Alg M1

- Materials coated with Fe and alginate : the highest growth of microbial biomass
- Fe or alginate may have created a suitable nutrient source for bacteria

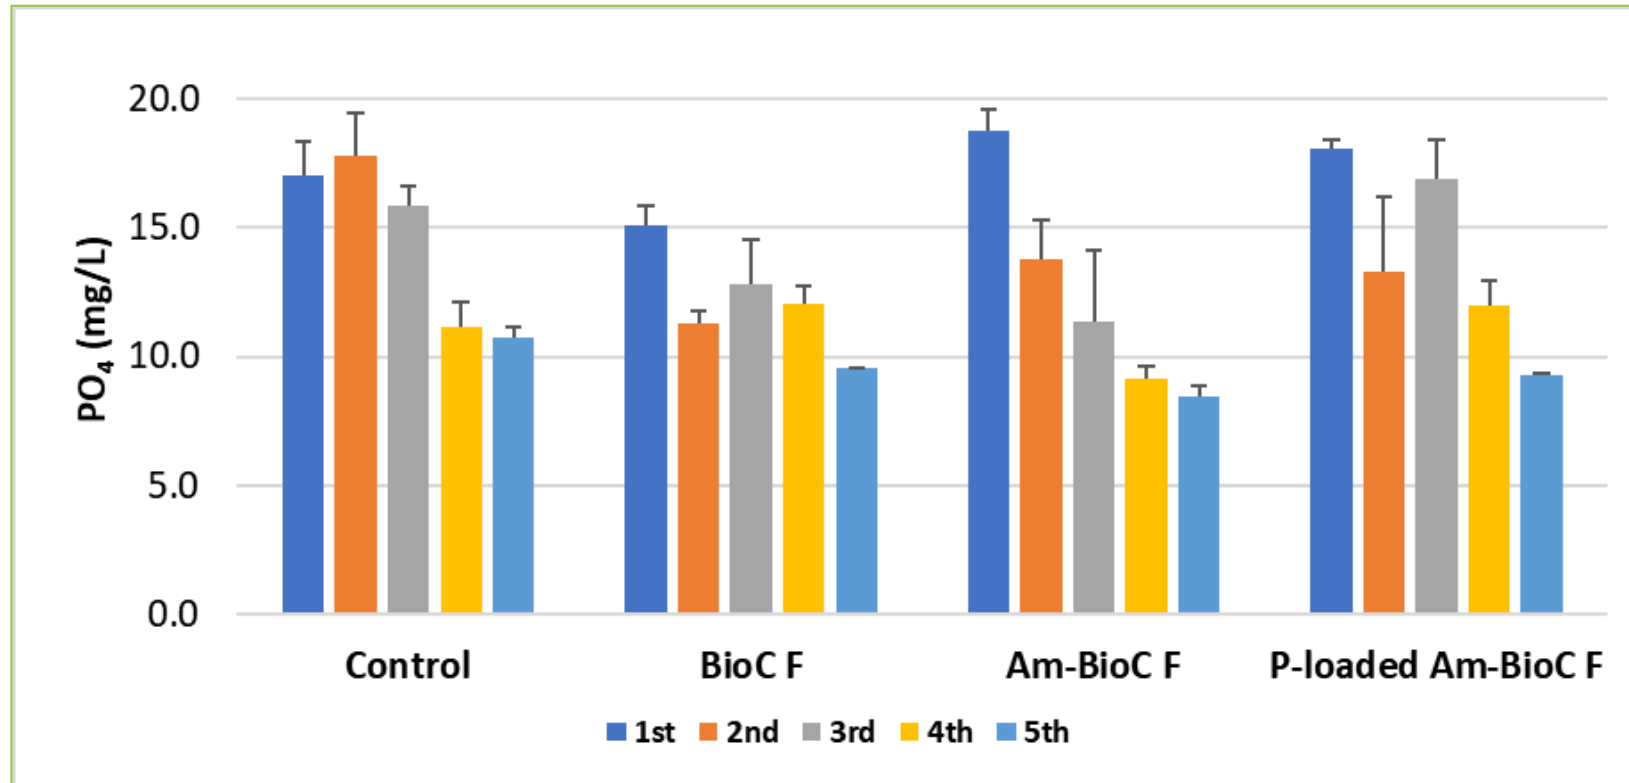

## P-loaded Am-BioC F

stimulated by the coexistence of phosphate and Fe used as nutrients in biofilm growth

BioC F - Images (spatial distribution) by confocal laser scanning microscopy (CLSM)

## PO<sub>4</sub> release in soil by P-loaded biochar

**Total average of leached PO<sub>4</sub> concentration of 5 cycles:** BioC F - the lowest ( $12.2 \pm 0.6$  mg/L)  
Control - the highest ( $14.5 \pm 0.5$  mg/L)

Nutrient loss prevention was not visible under the examined condition in nutrient-rich soils

# Growth of *Arabidopsis thaliana*

Control (soil)

Soil + Am-BioC F

Soil + P-loaded Am-BioC F

12 days after the transplant: Bolting/Flowering phase

Delayed flowering was observed in plants treated with Fe-coated biochar 4-5 days after Control

15 days after the transplant: Maturing silique

→ prolonged their vegetative stage to ensure the fruiting cycle

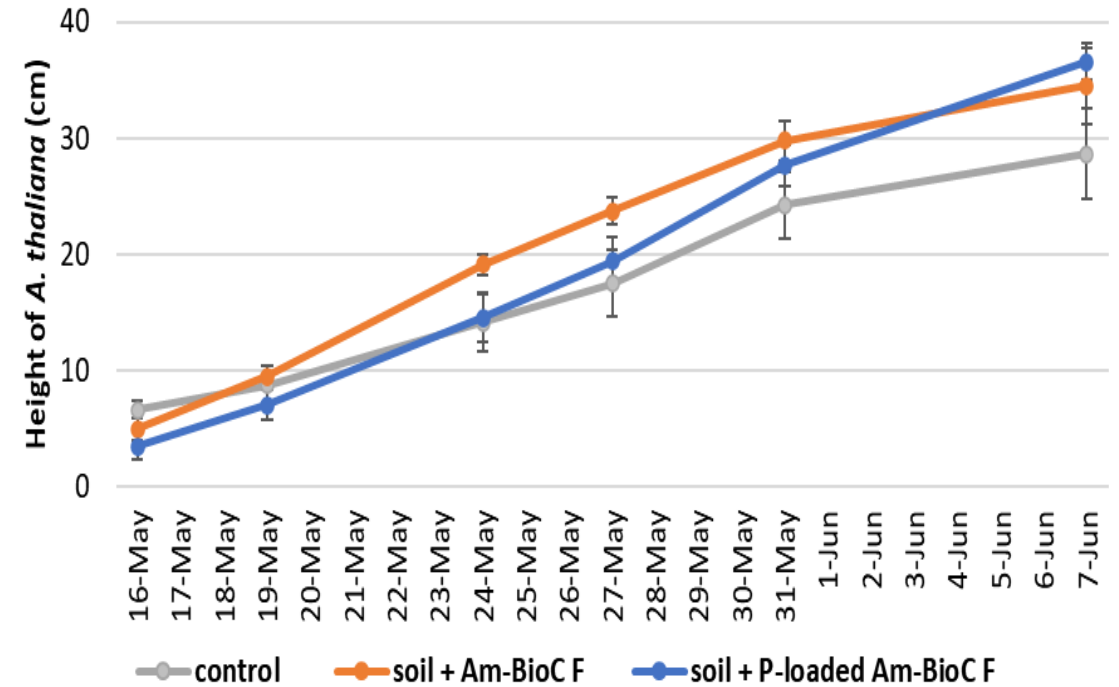

Control (soil)

Soil + Am-BioC F

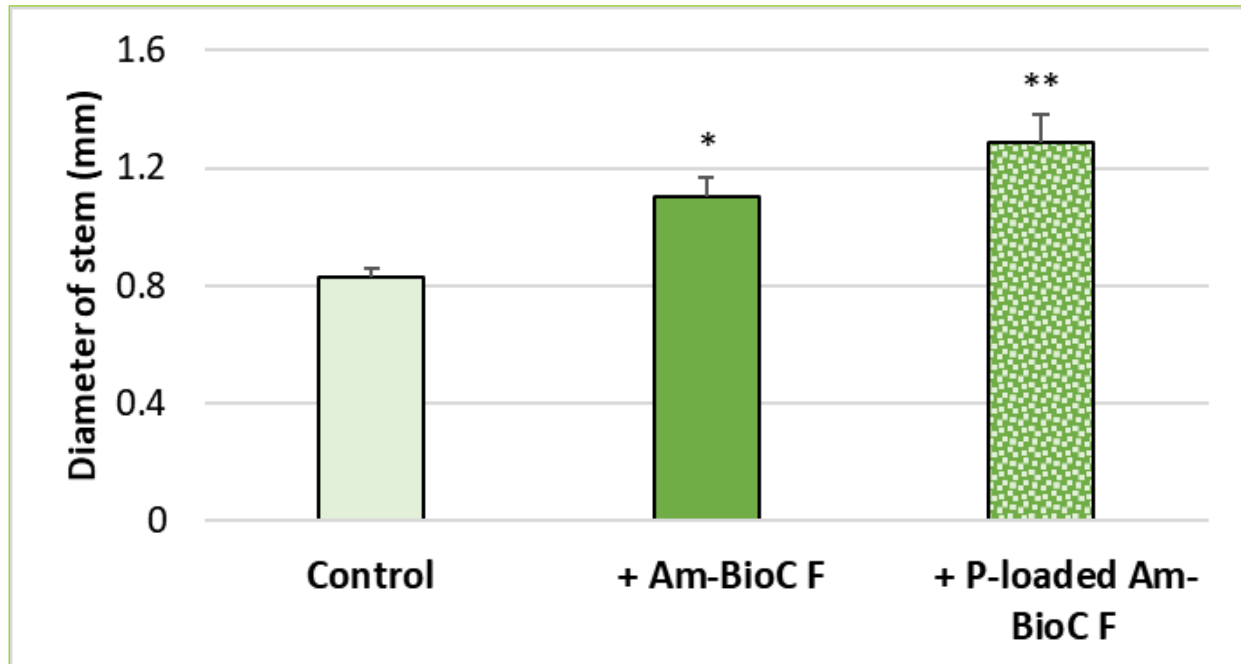

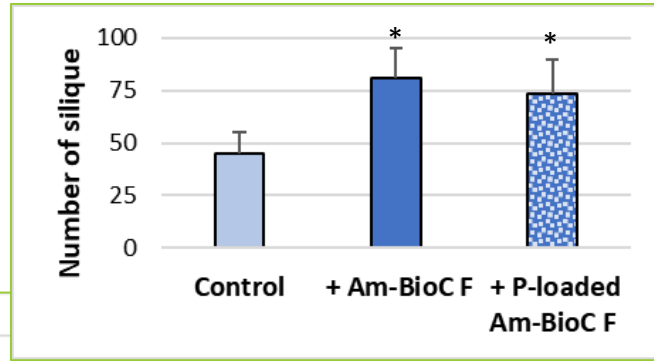

Soil + P-loaded Am-BioC F

1 month after the transplant: Used for morpho-anatomical analyzes

# Length of silique and diameter of stem

Plants grown on soil enriched with Fe-coated biochar (with and without P)

→ a statistically significant difference (P-loaded Am-BioC F:  $p < 0.01$ , Am-BioC F:  $p < 0.05$ ) compared to Control

# CONCLUSION

## Optimization of materials

- Am-BioC F: removal efficiency of 99%,  $q_{\max}$  equal to 7.1 mg/g
- Gel-coated materials: ↓ adsorption (alginate > agarose)
- During consecutive cycles : a drastic ∇ in P adsorption efficiency (in real matrices)

## Microbial biomass on materials

- (wastewater treatment system) Aka-BioC Alg M1: highest microbial biomass growth
- P-loaded Am-BioC F: highest abundance of bacteria compared to the control

## Growth of *Arabidopsis thaliana* with materials

- Plants grown on soil treated with Fe-coated biochar (with, without P): statistically significant difference (with P:  $p < 0.01$ , without P:  $p < 0.05$ ) compared to Control (lengths & numbers of siliques, stem diameter)

## Background

Water bodies contaminated by phosphate

Treatment to avoid eutrophication

Phosphorus (P): critical raw material

P recovery and recycling

Biochar

Fe-coating

Modified materials

PO<sub>4</sub><sup>3-</sup> Adsorption

*Arabidopsis thaliana*

Amendment

P - loaded materials

## Fe-coated Biochar

Optimization of materials to enhance the phosphate adsorption capacity → real "traps" for the phosphorus present in water

## Collaboration network

Sapienza University – Water Research Institute (IRSA-CNR)

Collaboration with municipalities, local authorities and protected areas managers → will provide a good network to facilitate its application

## Laboratory & real water exposure

The study was carried from both lab experiments and field

## Interdisciplinary approach

Chemistry, botany, microbiology, environmental science

## Tandem-style research

Optimization of a material that adsorbs P present in water

Its reuse as an amendment

## Circular economy

Green materials like biochar, once enriched with phosphate in eutrophicated environment, can then find direct use as fertilizers
